

Local zodiacal light: inside the Sun's dust cloud

the grain, magnified in its scattering plane

sightline 30° above the ecliptic (β), drawn projected; its solar elongation is 128° drawn at $\lambda - \lambda_{\odot} = -135^{\circ}$; the table is symmetric in its sign

Leinert table inputs: β , $|\lambda - \lambda_{\odot}|$, observer distance, wavelength

Exozodiacal light: far outside the host's disk

(b) side on: inclination i

(c) projected image

model inputs: density $n(r, z)$, phase $p(\Theta)$, orientation (i , position angle), stellar luminosity $L_{\star}$, distance D
